CIS 121—Data Structures and Algorithms with Java—Fall 2015

Master Theorem Lab—TBD

Learning Goals

During this lab, you will:

- review the Simplified Master Theorem
- solve recurrences by iteration and using the S.M.T.
- identify recurrences that can not be solved using the S.M.T.

Simplified Master Theorem

The **master theorem** is a powerful tool in the analysis and classification of recurrences. It may be used to easily *classify* recurrences that might otherwise be very time-consuming!

Simplified Master Theorem

Given a recurrence $T(n)$ of the form,

$$T(n) = \begin{cases} c & n < c_1 \\ aT(n/b) + \Theta(n^i) & n \geq c_1 \end{cases}$$

Case I: If $a > b^i$ then $T(n) = \Theta(n^{\log_b a})$.

Case II: If $a = b^i$ then $T(n) = \Theta(n^i \log_b n)$.

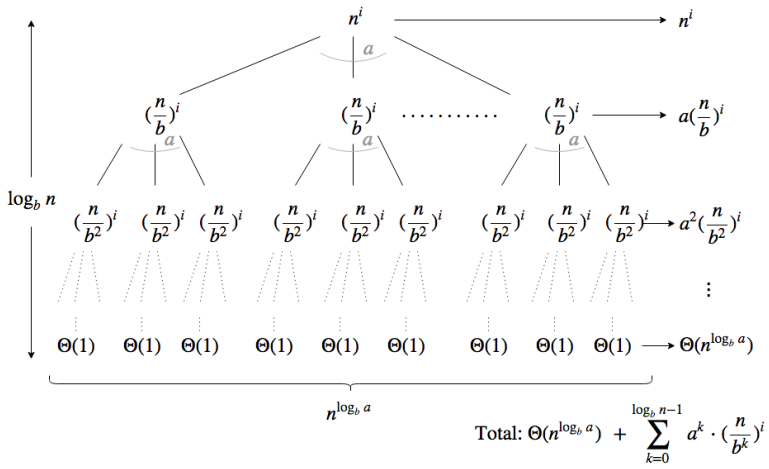
Case III: If $a < b^i$ then $T(n) = \Theta(n^i)$.

This probably seems very magical and hand-wavy. But we're computer scientists, so let's delve in and figure this out. Let us assume here that n is some power of b.

You don't need to be a wizard to understand the master theorem!

Understanding the S.M.T.

To understand why the S.M.T. works, let's draw out the recurrence tree for $T(n)$.



Depicted above is a tree-representation of the work performed at each level of iteration in the recurrence.

As shown in the diagram on the next page, at the kth level of iteration, there are a^k subdivisions of $(n/b^k)^i$ work. Therefore, at the bottom-most level there are $a^{\log_b n}$ subdivisions of $(n/b^{\log_b n})^i = 1$ work. Recall that by the properties of logarithms, $a^{\log_b n} = n^{\log_b a}$ — so we can switch the base and the contents of the log.

We can therefore write the total amount of work represented by the recurrence $T(n)$ as,

$$\text{Total Work: } \Theta(n^{\log_b a}) + \sum_{k=0}^{\log_b n-1} a^k \cdot (\frac{n}{b^k})^i$$

So what does this mean in the three cases shown in the simplified master theorem?

In the case where $a > b^i$, the work done at the leaves *heavily* outgrows that done at the root. That is, $n^{\log_b a}$ is the dominating term in the sum and the total work is therefore $\Theta(n^{\log_b a})$.

In the case where $a = b^i$, the work done at each level is the same and the total work is just the height of the tree multiplied by the work at each level: $\Theta(n^i \log_b n)$.

In the case where $a < b^i$, then the work done at each subsequent level decreases with respect to the root, and the work done at the root dominates: $\Theta(n^i)$.

Tada! By drawing the recurrence tree and summing the total work performed at each level, we were able to find general expressions for the recurrence solutions for each case of the S.M.T.

Problems

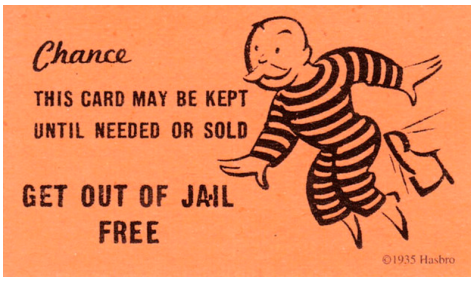
Problem 1

We will continue to develop our understanding of the Simplified Master Theorem. For each of these three common recurrences, you should first practice solving the recurrence by expanding (telescoping, or another preferred method), then apply the above method to derive the same recurrence.
Also, you should be able to name some common algorithms that correspond to these recurrence relations!

- $T(n) = T(\frac{n}{2}) + c$
- $T(n) = 2T(\frac{n}{2}) + c$
- $T(n) = 2T(\frac{n}{2}) + n$

Problem 2

Get out of jail free? The Master Theorem is certainly useful as we saw in the recurrences in problem 1. However, there are many recurrences that cannot be solved using this method. In this problem, examine



Maybe not the answer to all your problems

the pseudocode, and determine the recurrence relation. State whether or not it can be solved using the simplified master theorem.

```
    public String reverseString(String s) {
        if (s.length() == 0) {
            return s;
        }
        return reverseString(s.substring(1)) + s.charAt(0)
    }
```

```
def fib(n):
        if n == 1 or n == 0:
            return n
        return fib(n-1) + fib(n-2)
```

```
def powerof2(n)
        if n = 0
            return 1
        else
            tmp = powerof2(floor(n/2))
            if (n is even) then
              return tmp * tmp
            else
              return 2 * tmp * tmp
```
